# Soils under pressure: Essential services and global degradation

## Soil ecosystem services

- Around one-third of the world's soils are already degraded.
- If current practices continue, most soils could be at risk by 2050 (FAO, 2015).

## Main causes of soil degradation

Simplified and intensive farming practices can reduce soil biodiversity, organic matter content and soil structure, thereby weakening the natural capacity of soils to support food production.

# What exactly are cover crops?

## Cover Crop

German: Zwischenfrucht

French: cultures de couverture

Spanish/Portuguese: cultivos de cobertura/culturas de cobertura

- A crop that is generally not intended for harvest, but is grown to improve soil quality and fertility, prevent soil erosion, nutrient losses and weed growth, reduce pests, and maintain biodiversity
- They are usually planted between main crops, after harvest, or during periods when the soil would otherwise remain bare.

## Cover cropping is an old practice

- In traditional agricultural systems, cover crops were widely used before the broad adoption of synthetic fertilisers, heavy machinery and pesticides.
- Cover cropping appeared in many forms that supported soil health and productivity.

# Why use cover crops?

## Key ecosystem services of cover

**Carbon sequestration**

CO<sub>2</sub> captured and stored in soil

**Improves soil structure**

Stable aggregates, less compaction

**Supports soil life**

Microbes, fungi & earthworms

**Nutrient cycling**

N, P & S cycled to plant roots

Cover crops provide multiple **regulating, supporting and provisioning** ecosystem services.

**Water infiltration & retention**

More infiltration, more water held in soil

**Erosion control**

Protects soil from rain splash and wind

**Weed suppression**

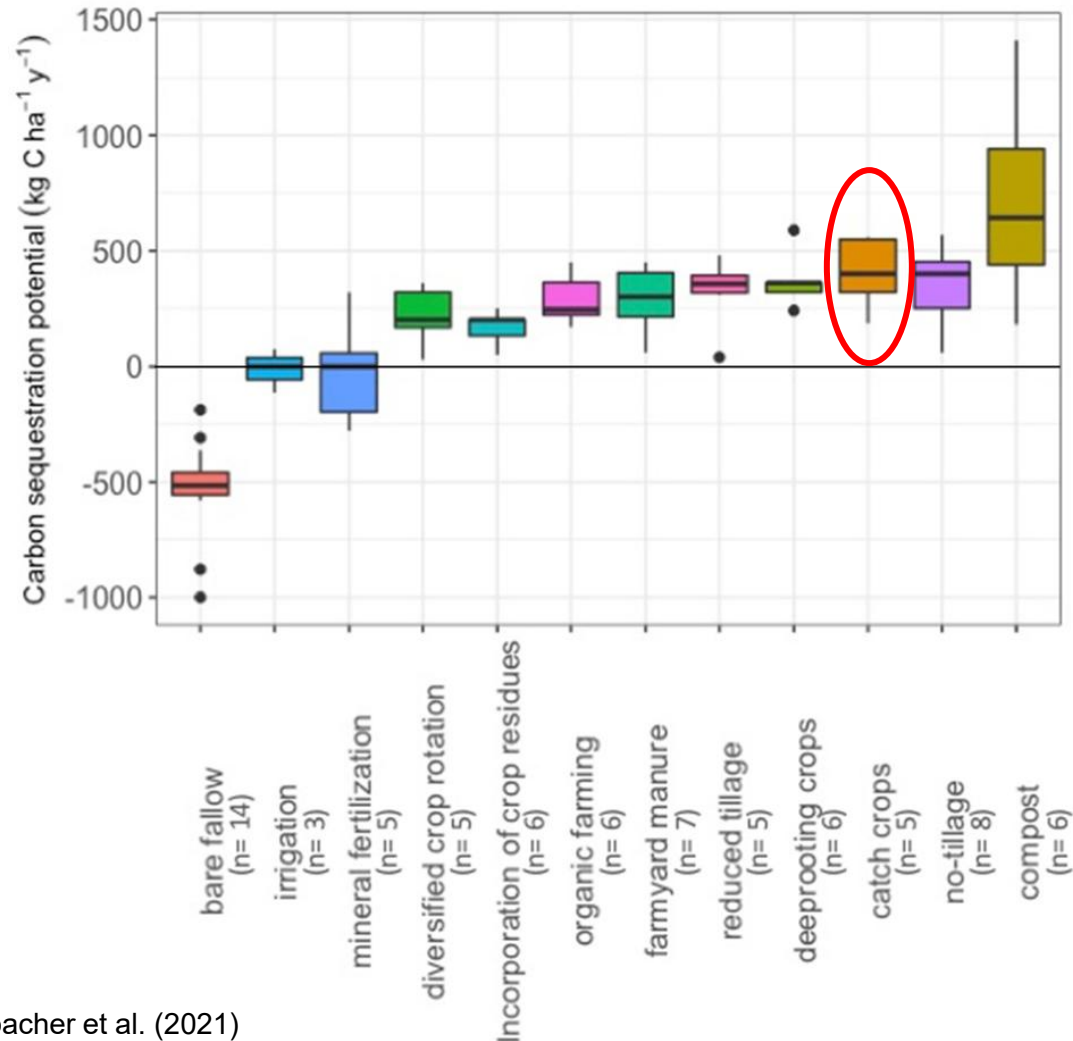

Dense canopy shades out weeds

**Supports biodiversity**

Pollinators & beneficial insects above and diverse life below ground

# Why use cover crops for carbon sequestration?

Besides contributing to carbon sequestration, cover cropping is also:

- cost-effective
- feasible in many farming systems

# How do cover crops fit into the rotation?

## Common simple 2-year rotation cereal-maize

Grass monoculture

Diversification

Crimson clover  
*Trifolium incarnatum*

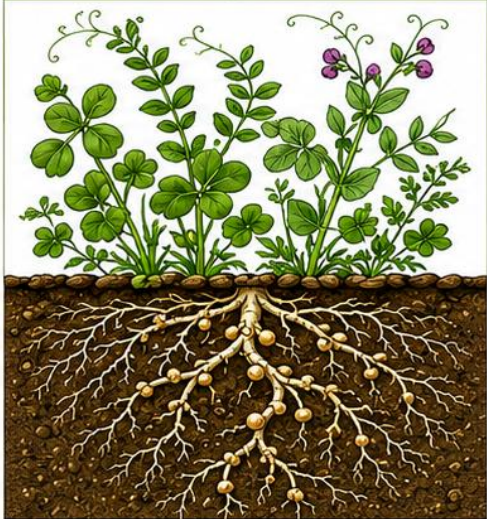

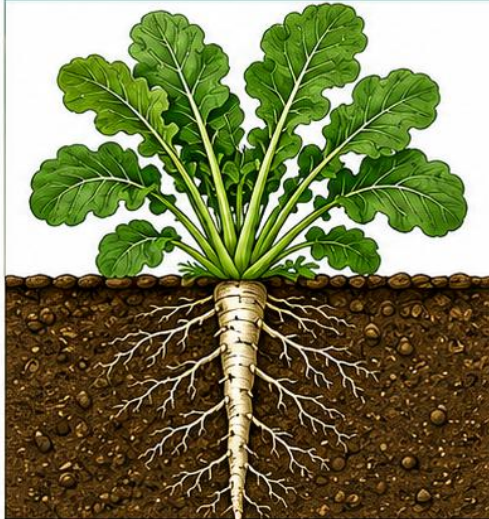

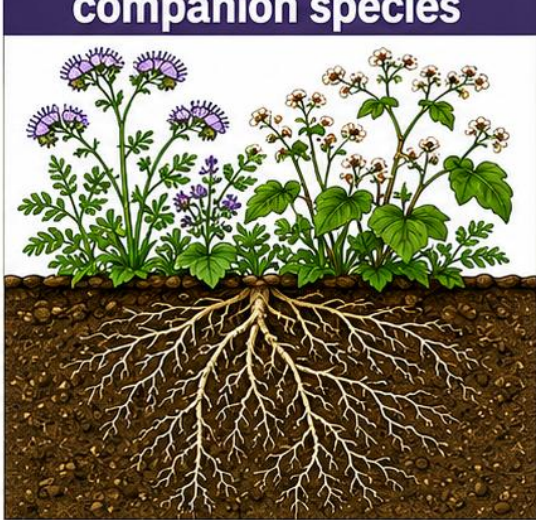

Buckwheat  
*Fagopyrum esculentum*

# Main functional groups of cover crops

1. Grasses / Cereals	2. Legumes	3. Brassicas	4. Broadleaf companion species
			
<ul style="list-style-type: none"><li> High biomass</li><li> Dense soil cover</li><li> Fibrous roots improve structure</li></ul> <p><i>e.g. rye, oats, sorghum-sudangrass</i></p>	<ul style="list-style-type: none"><li> Nitrogen fixation</li><li> High-quality residues</li><li> Root nodules support soil fertility</li></ul> <p><i>e.g. vetch, clover, peas</i></p>	<ul style="list-style-type: none"><li> Deep taproot</li><li> Nutrient scavenging</li><li> Helps relieve compaction</li></ul> <p><i>e.g. radish, mustard, rapeseed</i></p>	<ul style="list-style-type: none"><li> Rapid cover</li><li> Supports biodiversity</li><li> Mobilises nutrients</li></ul> <p><i>e.g. buckwheat, phacelia, niger</i></p>

# Cover crop mixtures

# Soil Organic Carbon (SOC) — A key indicator of soil fertility

**Soil organic carbon (SOC)** is the carbon component of soil organic matter. It plays a central role in soil health and fertility.

SOC improves **soil structure**, supports **nutrient cycling**, increases **water retention** and stimulates **biological activity**, making soils **more fertile, resilient and productive**.

# Carbon is stored in plant biomass

**COVER CROPS GROW  
USING SUNLIGHT, WATER  
AND NUTRIENTS.**

**GROWTH DEPENDS ON:**

WEATHER

SPECIES

SOWING DATE

- Cover crops can produce 2–10 t of aboveground dry matter per hectare within 3–4 months.
- Total carbon content is approximately 30–40%.
- This corresponds to about 0.6–3 t C ha<sup>-1</sup> temporarily stored in plant biomass

# Cover crop roots release carbon into the soil

## CARBON ADDITION TO SOIL VIA ROOTS

- Roots release carbon-rich exudates (sugars, amino acids) into the soil through rhizodeposition.
- Rhizodeposition represents 10-25 % of the total cover crop carbon input (Hansen et al., 2025).
- These carbon compounds feed soil microbes directly and can contribute to the formation of soil organic matter.

# Cover crop aboveground biomass is terminated

Photo: R. Leskovšek, 2020

- Aboveground biomass is left on the soil surface or incorporated into the soil.
- Plant residues decompose over time.

# Low C/N residues decompose rapidly

**MICROBES BREAK DOWN  
PLANT MATERIAL.**

**CARBON IS USED  
BY MICROBES AND  
RELEASED BACK TO  
THE AIR AS CO<sub>2</sub>.**

CO<sub>2</sub>

**LOW C/N RATIO (≈10–20)**

**Examples: Legumes**  
*(clover, vetch, pea)*

- Fast decomposition
- Rapid N release (mineralization)
- Boosts crop nutrition
- Less carbon stored long-term

**Feeds the next crop  
(N supply)**

# High C/N residues decompose more slowly

**MICROBES BREAK DOWN  
PLANT MATERIAL.**

**CARBON IS USED  
BY MICROBES AND  
RELEASED BACK TO  
THE AIR AS CO<sub>2</sub>.**

CO<sub>2</sub>

**HIGH C/N RATIO (≈25–60)**

**Examples: Grasses  
(rye, oats, triticale)**

- Slow decomposition
- Temporary N immobilization
- More stable soil carbon formation

**Builds soil carbon  
(long-term storage)**

# Soil carbon storage is a slow process

PART OF THE CARBON IS  
STABILIZED AND STORED IN  
SOIL ORGANIC MATTER.

ONLY ABOUT

**10-20%**

OF THE CARBON INPUT BECOMES  
STABLE SOIL CARBON.

**80–85% of carbon is lost as:**

- microbial respiration
- CO<sub>2</sub> (mineralization)

# Indirect effects of cover crops on carbon sequestration

## Prevention of water and wind erosion

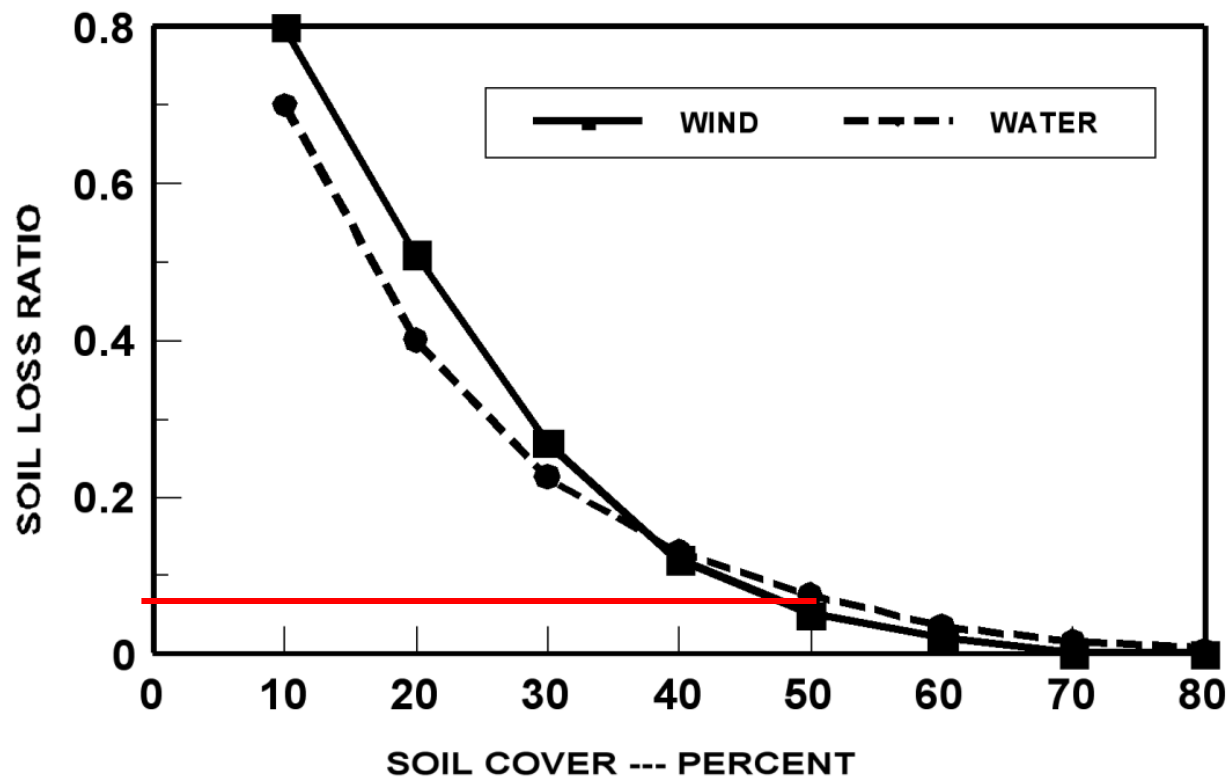

Source and photo: Lešnik, 2022

Source and photo: Kisić, 2022

# Cover crops provide soil cover and reduce soil loss

- Compared with bare soil, 50% soil cover may reduce soil losses by up to tenfold

50% plant cover is usually reached 3–4 weeks after sowing.

Soil cover → Reduced **temperature fluctuations** → slower decomposition

## Take Home messages

- Healthy soils need living roots and continuous cover.
- Cover crops offer a practical, feasible and multifunctional solution.
- Their greatest potential lies in well-designed mixtures of functional groups.
- The strongest benefits develop over time, through repeated use and good integration into crop rotations.
- In future farming systems, cover crops should become a standard practice for soil protection and resilience.

# What is future of cover cropping?

-  **1 Precision mixture design**  
tailored species mixes  
for specific goals
-  **2 Smart establishment**  
drones, robotics and  
improved seeding
-  **3 Real-time monitoring**  
soil sensors, remote sensing  
and field diagnostics
-  **4 Decision support & AI**  
better timing, management  
and adaptation
-  **5 A standard practice in  
digital climate-smart farming**  
integrated with data-driven  
farm management

# LIFE4ADAPT project

## Aim:

To demonstrate agricultural adaptation strategies to climate change, including reduced tillage, precision irrigation, **cover crops** and other practices.

## Cover cropping activities:

- Improving soil cover
- Optimising cover crop mixtures with legumes
- Improving methods of cover crop establishment, such as undersowing and drone seeding
